## NeoColab\_REC\_CS23221\_Python Programming

### REC\_Python\_Week 4\_CY

Attempt : 1  
Total Mark : 40  
Marks Obtained : 37.5

### Section 1 : Coding

#### 1. Problem Statement

Arjun is working on a mathematical tool to manipulate lists of numbers. He needs a program that reads a list of integers and generates two lists: one containing the squares of the input numbers, and another containing the cubes. Arjun wants to use lambda functions for both tasks.

Write a program that computes the square and cube of each number in the input list using lambda functions.

#### ***Input Format***

The input consists of a single line of space-separated integers representing the list of input numbers.

#### ***Output Format***

The first line contains a list of the squared values of the input numbers.

The second line contains a list of the cubed values of the input numbers.

Refer to the sample output for the formatting specifications.

### **Sample Test Case**

Input: 1 2 3

Output: [1, 4, 9]

[1, 8, 27]

### **Answer**

```
# You are using Python
arr = list(map(int, input().split()))
square = list(map(lambda x: x**2, arr))
cube = list(map(lambda x: x**3, arr))
print(square)
print(cube)
```

**Status :** Correct

**Marks : 10/10**

## **2. Problem Statement**

Implement a program for a retail store that needs to find the highest even price in a list of product prices. Your goal is to efficiently determine the maximum even price from a series of product prices. Utilize the `max()` inbuilt function in the program.

For example, if the prices are 10 15 24 8 37 16, the even prices are 10 24 8 16. So, the maximum even price is 24.

### **Input Format**

The input consists of a series of product prices separated by a space.

The prices should be entered as a space-separated string of numbers.

### **Output Format**

If there are even prices in the input, the output prints "The maximum even price is:" followed by the maximum even price.

If there are no even prices in the input, the output prints "No even prices were found".

Refer to the sample output for formatting specifications.

### **Sample Test Case**

Input: 10 15 24 8 37 16

Output: The maximum even price is: 24

### **Answer**

```
# You are using Python
input_prices = input()
prices = list(map(int, input_prices.split()))
even_prices = [price for price in prices if price % 2 == 0]
if even_prices:
    print("The maximum even price is:",max(even_prices))
else:
    print("No even prices were found")
```

**Status :** Correct

**Marks : 10/10**

### **3. Problem Statement**

Meena is analyzing a list of integers and needs to count how many numbers in the list are even and how many are odd. She decides to use lambda functions to filter the even and odd numbers from the list.

Write a program that takes a list of integers, counts the number of even and odd numbers using lambda functions, and prints the results.

### **Input Format**

The first line contains an integer n, representing the number of integers in the list.

The second line contains n space-separated integers.

### **Output Format**

The first line of output prints an integer representing the count of even numbers.

The second line of output prints an integer representing the count of odd numbers.

Refer to the sample output for the formatting specifications.

### **Sample Test Case**

Input: 7

12 34 56 78 98 65 23

Output: 5

2

### **Answer**

# You are using Python

```
n = int(input())
```

```
nums = list(map(int, input().split()))
```

```
even_numbers = list(filter(lambda x: x % 2 == 0, nums))
```

```
odd_numbers = list(filter(lambda x: x % 2 != 0, nums))
```

```
print(len(even_numbers))
```

```
print(len(odd_numbers))
```

**Status :** Correct

**Marks :** 10/10

## **4. Problem Statement**

Amrita is developing a password strength checker for her website. She wants the checker to consider the length and the diversity of characters used in the password. A strong password should be long and include a mix of character types: uppercase, lowercase, digits, and special symbols.

She also wants the feedback to be user-friendly, so she wants to include the actual password in the output. Help Amrita finish this password checker using Python's built-in string methods.

Character Types Considered:

Lowercase letters (a-z) Uppercase letters (A-Z) Digits (0-9) Special characters (from string.punctuation, e.g. @, !, #, \$)

### ***Input Format***

The input consists of a single string representing the user's password.

### ***Output Format***

The program prints the strength of the password in this format:

If the password length < 6 characters or fewer than 2 of the 4 character types, the output prints "<password> is Weak"

If password length  $\geq 6$  and at least 2 different character types, the output prints "<password> is Moderate"

If Password length  $\geq 10$  and all 4 character types present, the output prints "<password> is Strong"

Refer to the sample output for formatting specifications.

### ***Sample Test Case***

Input: password123

Output: password123 is Moderate

### ***Answer***

```
# You are using Python
password = input()
has_lower = False
has_upper = False
has_digit = False
for ch in password:
    if ch.islower():
        has_lower = True
    elif ch.isupper():
        has_upper = True
    elif ch.isdigit():
```

```
has_digit = True
length = len(password)
criteria_met = has_lower + has_upper + has_digit
if length >= 8 and criteria_met == 3:
    strength = "Strong"
elif length >= 6 and criteria_met >= 2:
    strength = "Moderate"
else:
    strength = "Weak"
print(f"{password} is {strength}")
```

**Status :** Partially correct

**Marks :** 7.5/10
